1 **Abstract:**

2 **Background/Context:** Spinal sarcomas are aggressive tumors that originate from cells of  
3 mesenchymal origin, specifically fat, cartilage, bone and muscle. They are high-grade lesions, and  
4 treatment of spinal sarcomas can involve chemotherapy, radiation therapy, and surgery. In the  
5 appendicular skeleton, sarcomas are often treated with amputation, however in the spinal  
6 column, surgical resection poses a unique set of challenges.

7  
8 **Purpose:** Large-scale studies of spinal sarcoma are needed to better understand optimal  
9 treatment regimens and the impact of en bloc or intralesional resection on patient outcome.

10  
11 **Study design/setting:** A cohort of 25 sarcoma patients treated at a single medical institution  
12 between 2002 and 2012 was reviewed.

13  
14 **Patient Sample and Outcome measures:** Patients were classified by tumor type for subgroup  
15 analysis, including chondrosarcoma, osteosarcoma, and other malignant spinal sarcoma.  
16 Demographic data for review included patient age, tumor type, tumor location, surgery type,  
17 exposure to chemotherapy and radiation therapy.

18  
19 **Methods:** Survival statistics and Kaplan-Meier curves were calculated using GraphPad Prism  
20 5.0. The threshold for statistical significance was set at  $p < 0.05$ . Unpaired, two-tailed, equal  
21 variance t-tests were performed for statistical analyses in Microsoft Excel 2010. Portions of this  
22 work were supported by the AOSpine Primary Tumor Knowledge Forum. The authors report no  
23 potential conflicts of interest related to this manuscript.

1 **Results:** Twenty-five patients with spinal sarcomas were treated over the ten-year period.  
2 Diagnosis included chondrosarcoma (n=9), osteosarcoma (n=4) and other sarcoma (n=12). Mean  
3 age at the time of diagnosis was 42 years. Pain was present at the time of diagnosis in 92% of  
4 patients. Median survival after surgery was 59.5 months for chondrosarcoma, undefined for other  
5 sarcomas and 16.8 months for osteosarcoma. Median survival following en bloc resection was  
6 undefined. Median survival following intralesional resection was 17.8 months. The difference in  
7 median survival between en bloc and intralesional resection was statistically significant  
8 (p=0.049).

9  
10 **Conclusion:** The authors report the largest cohort of patients with spinal sarcoma. Median  
11 survival in this cohort was longest for patients with sarcomas of varying pathology. Median  
12 survival was longer for chondrosarcoma. En bloc resection demonstrated a survival advantage  
13 over intralesional resection. Long term follow-up is needed for patients with spinal sarcoma to  
14 establish definitive survival data.

15  
16 **Key Words:** Sarcoma; Osteosarcoma; Chondrosarcoma; Outcome

17

## 1 **Introduction:**

2 Spinal sarcomas are a rare group of spinal malignancies that are associated with high  
3 rates of morbidity and mortality. Epidemiological studies of spinal sarcomas, such as from the  
4 Surveillance Epidemiology and End Results (SEER) database cancer statistics review from  
5 1975-2009, demonstrate that sarcomas represent less than 5% of all osseous neoplasms and less  
6 than 0.2% of all new cancers.<sup>1,2</sup> Sarcomas can occur in a variety of osseous regions throughout  
7 the body. However, sarcomas of the spine and surrounding structures often elicit debilitating  
8 consequences due to severe focal pain and neurological morbidity.

9 Chondrosarcoma represents 25% of sarcomatous tumors and increases in likelihood in  
10 patients over the age of 50.<sup>3,4,5,6</sup> Chondrosarcomas are part of a family of malignant tumors  
11 where the cells differentiate uncontrollably into cartilaginous tissue. It is further classified as  
12 central, peripheral, or periosteal, with mesenchymal and clear cell variants.<sup>7</sup> Osteosarcoma tends  
13 to be more common, representing 35% of all sarcomas and 3 to 15% of all primary spine tumors.  
14 There exist a variety of subtypes including conventional osteosarcomas, telangiectatic, small-  
15 cell, giant-cell, epithelioid, and osteoblastoma-like osteosarcomas<sup>8,9</sup>

16 Whereas previous studies have been confined by limited patient data or the size of their  
17 patient population, this database of spinal sarcomas is comprised of 25 spinal sarcoma patients  
18 who underwent surgical resection at a single institution from 2002 to 2012. We investigate the  
19 impact of en bloc resection on patient outcome through analyzing a single institutions surgical  
20 management of spinal sarcomas over the last decade. While the SEER database provided  
21 invaluable epidemiological data of 1378 sarcoma patients, it did not stratify outcomes based on  
22 surgical approach from each surgical institution separately. Thus, by looking only at patients  
23 from a single institution during a single decade, this study allows for a controlled standard of

1 care, which we hope may then be used by neurosurgical and orthopedic spinal surgeons to  
2 determine functional and oncologic survival data for a variety of surgical techniques and  
3 treatments.

#### 5 **Methods:**

##### 6 *Study population*

7 Demographic, treatment and outcome data was collected retrospectively from the  
8 electronic medical record following protocols dictated by the Institutional Review Board (IRB  
9 application NA\_00066200). 25 consecutive patients with histology-confirmed spinal sarcomas  
10 treated at a single institution from 2002-2012 were reviewed. Patient medical records, including  
11 clinic notes, primary radiographs, computed tomography (CT) scans and magnetic resonance  
12 imaging (MRI) were reviewed. Pathology reports were also reviewed.

##### 14 *Study criteria*

15 All patients included in this study presented with histologically confirmed sarcoma of the  
16 spine. Covariates identified were epidemiological data such as age, gender, length of  
17 hospitalization, location of sarcoma, number of spinal levels involved, surgical approach, tumor  
18 volume, pathology of sarcoma, extent of resection, pain at diagnosis, Frankel score, presence of  
19 myelopathy and caudaequina, adjunctive treatment, local recurrence, and overall survival. The  
20 diagnosis of other sarcoma included epithelioid sarcoma (n=3), pleomorphic undifferentiated  
21 sarcoma (n=2), spindle cell sarcoma (n=2), alveolar soft part sarcoma (n=1), unusual low grade  
22 sarcoma (n=1), postradiation sarcoma (n=1), fibromyxoid sarcoma (n=1) and Ewing sarcoma  
23 (n=1).

1 Surgical approach was recorded from operative notes. Pain at diagnosis was self-reported  
2 by patients at any pre-operative clinic visit within 3 months of surgery. The number of spinal  
3 levels involved and the presence or absence of a pathologic fracture was determined from the  
4 radiology reports of preoperative CT and MRI scans.

5 Vital statistics were recorded from the Social Security Death Master File accessed online.  
6 All vital statistics reflect the status of patients as of July 31, 2012. Survival data for non-US  
7 citizens was recorded as unknown. Recurrence data is recorded for all patients at the last clinical  
8 follow up. Recurrence was determined from post-operative neurosurgery clinic notes reporting  
9 the neurosurgeon's interpretation of radiographic recurrence at the time of last follow up.

10 Tumor size and volume was recorded from primary review of preoperative MRI or CT  
11 scans. Volume was calculated via the formula for the volume of an ellipsoid ( $(4\pi/3)r^1r^2r^3$ ). Radii  
12 were taken as one-half the cranial-caudal, anterior-posterior and lateral measurements of the  
13 tumor. Measured values were corroborated with radiology reports.

14 Following surgery, patients were seen at one month then at three, six, nine and twelve  
15 months. Patients were followed every six months in the second year, then yearly, or as clinical  
16 progression dictated their plan of care. MRI with and without contrast was used to evaluate  
17 tumor recurrence at the time of clinical follow-up. Early complications, defined as occurring  
18 within thirty days postoperatively, and late complications, defined as occurring after thirty days  
19 postoperatively were recorded.

## 20 21 *Statistical Analysis*

22 Survival statistics and Kaplan-Meier curves were calculated using GraphPad Prism 5.0  
23 (GraphPad, La Jolla, CA). The threshold for statistical significance was set at  $p < 0.05$ . Unpaired,

1 two-tailed, equal variance t-tests were performed for statistical analyses in Microsoft Excel 2010.  
2 95% confidence intervals were determined using the Confidence Interval Calculator for  
3 Proportions (Online, McCallum-Layton; 2010).

4

5

## 6 **Results:**

### 7 *Patient Population*

8 Twenty-five patients with spinal sarcomas were treated over the ten-year period. Mean  
9 age at the time of diagnosis was 42 years (range 17-75 years) and the disease was found  
10 predominantly in women (56%). The mean age at presentation differed by tumor type.  
11 Chondrosarcoma (46.7 years  $\pm$ 10.4 years) and osteosarcoma (48.8 years  $\pm$  23.5 years) presented  
12 at an older mean age than other sarcomas (36.2 years  $\pm$ 18.0 years). Median length of stay after  
13 surgery was 16 days (range 4 – 52 days). Median follow up time was 11.8 months (range 0.1 –  
14 71.6 months).

15

### 16 *Clinical Presentation*

17 Pain was present at the time of diagnosis of a majority of patients (92%). Pathological  
18 fractures were typically not present at the time of diagnosis (12%). Myelopathy was present in a  
19 majority of patients (68%), more so in cases involving chondrosarcoma (67%) and osteosarcoma  
20 (100%) than other sarcomas (58%). Cauda equina was absent in a majority of patients (16%).  
21 Ten patients (40 %) had undergone a previous spinal tumor resection. Pre-operative Frankel  
22 scores of the sarcoma patients were C (28%), D (36%), and E (36%).

23

### 1 *Surgical Approach*

2 Chondrosarcoma and osteosarcoma were found predominantly in the cervical, thoracic,  
3 or lumbar spine, while other sarcomas are more common in the sacral spine. The median  
4 number of vertebral levels involved was three (range 1-7). A posterior approach was used most  
5 commonly (56%) followed by surgeries involving both an anterior and posterior approach  
6 (40%). The most common procedure was a laminectomy or hemilaminectomy, which was  
7 performed in 15 cases (60%). The most common type of reconstruction used was an allograft  
8 (48%), followed by the use of a titanium cage (32%). Often times, chondrosarcoma patients  
9 underwent no form of reconstruction (60%).

10

### 11 *Adjuvant Treatment*

12 Adjuvant treatment was used in 15 cases (60%). Six patients received preoperative  
13 chemotherapy (24%), four received postoperative chemotherapy (16%), seven underwent pre-op  
14 radiation (28%), and ten underwent post-op radiation (40%). Local recurrence occurred in six  
15 cases (24%).

16

### 17 *Complications*

18 Complications noted earlier than thirty days postoperatively (early complications) and  
19 later than thirty days (late complications) were stratified by either en bloc resection or  
20 intralesional resection. In the En bloc resection group, five patients (33.3%) required reoperation  
21 secondary to wound dehiscence, and three patients (20%) developed deep venous thrombosis  
22 less than thirty days postoperatively. Greater than thirty days postoperatively, four patients  
23 (26.7%) required reoperation for three cases of wound dehiscence and one case of

1 instrumentation failure that resulted in loss of correction of deformity. The other two cases of  
2 instrument failure did not have any loss of deformity correction and no operative intervention  
3 was pursued. In the Intralesional resection group, two patients (30.0%) required reoperation  
4 secondary to wound dehiscence and postoperative hematoma, and one patient (10%) developed  
5 deep venous thrombosis less than thirty days postoperatively. Greater than thirty days postop,  
6 there was one complication of esophageal erosion requiring revision surgery to remove the  
7 cervical plate in the intralesional group. **(Table 1)**

8

### 9 *Patient Survival*

10 Median survival following surgery for chondrosarcoma was 59.5 months (range 0.2-70.6  
11 months), undefined for other sarcomas (range 0.2-26.5 months) and 16.8 months for  
12 osteosarcoma (range 0.5-28.5 months). **(Figure 1)** The difference in survival was not statistically  
13 significant on Mantel-Cox testing. ( $p=0.27$ ) Median survival following en bloc resection was  
14 undefined. Median survival following intralesional resection was 17.8 months. **(Figure 2)**  
15 Survival following en bloc resection was significantly different than survival after intralesional  
16 resection on Gehan-Breslow-Wilcoxon test ( $p = 0.049$ ). The survival difference was not  
17 statistically significant on Mantel-Cox testing ( $p=0.07$ ).

18

### 19 **Discussion:**

20 This subset of malignant spinal tumors encompasses chondrosarcomas, osteosarcomas, as  
21 well as a variety of other sarcomatous tumors including Ewings sarcoma. Although previous  
22 studies have examined the broad epidemiologic outcomes of patients at multiple institutions,  
23 these studies did not investigate outcomes relative to the specifics of treatment.<sup>10, 11, 12</sup> Our

1 review highlights the important aspects of surgical management, namely the benefit of en bloc  
2 resection for spinal sarcoma.

3         Surgical management of sarcomas is diverse, and is dependent on location of tumor  
4 burden. For example, the orthopedic literature recommends wide excision or amputation of  
5 extremity sarcoma when feasible, with use of adjuvant treatments such as phenol, radiation, and  
6 chemotherapy as needed <sup>13</sup>. En bloc strategies available to patients include corpectomy, sacral  
7 amputations, and finally hemipelvectomy <sup>14</sup>. However, surgical resection of spinal sarcomas  
8 cannot extend this concept of amputation at mobile spine levels due to the necessity of adjacent  
9 anatomical structures. The results of this study suggest that en bloc resection, when feasible,  
10 should be offered to patients with diverse sarcomatous pathologies in the spinal column in order  
11 to optimize patient survival.

12         Chondrosarcoma patients have shown to have a 5-year survival rate close to 70% and a  
13 median survival ranging from 70 to 160 months. <sup>15, 16, 17</sup> Our data showed a median survival of 60  
14 months. This variation can be accounted for in part by our small patient pool (10  
15 chondrosarcoma patients) and with not all patients reaching five years of follow up (median  
16 follow up 11.8 months, range 0.1 – 71.6). Osteosarcoma patients are shown to have a median  
17 survival ranging from 7 to 23 months. <sup>18, 19</sup> Our data demonstrates that the osteosarcoma patients  
18 had a median survival of almost 17 months. This is in accordance with previously published  
19 data from Schwab et al. who noted increased survival of 60 months in their cohort of 17 patients  
20 over 2 decades <sup>20</sup>.

21         Prior studies have shown that an en bloc resection of spinal sarcomas with adequate  
22 margins decreases recurrence rates. <sup>21, 22, 23</sup> However, a number of other studies have shown the  
23 dangers of an en bloc resection in the spine, including the increased morbidity of the procedure

1 and the varying difficulty in different locations of the spine.<sup>24, 25, 26</sup> Through our database, we  
2 have shown that en bloc resection of spinal sarcomas does increase patient survival as compared  
3 to purely intralesional resection (p = 0.049).

4 The authors acknowledge the limitations of this study. This study was limited by its small  
5 cohort size, which resulted in some of the trends observed not reaching statistical significance.  
6 Our findings add to the growing amount of sarcoma literature, with a focus on cancer varieties  
7 and surgical approaches. In the future, these studies can be utilized to provide a better quality of  
8 care to patients affected by the disease.

9  
10 **Conclusion:**

11 Sarcomas of the spine are a unique group of highly aggressive and malignant spinal  
12 tumors that represent a surgical and management challenge for the surgeon and the entire health  
13 care team. Reports continue to demonstrate a high morbidity and mortality in this population.  
14 However, the results of this study suggest that en bloc resection of these tumors, when possible,  
15 may increase patient survival. Continued improvement in surgical and adjuvant treatment will  
16 undoubtedly continue to further alter the survival curve for this population of spinal tumors.

17

1 **Figure Legends**

2

3 **Figure 1. Survival by pathology.** Median survival following surgery for chondrosarcoma was  
4 59.5 months (range 0.2-70.6 months), undefined for other sarcomas (range 0.2-26.5 months) and  
5 16.8 months for osteosarcoma (range 0.5-28.5 months). The difference in survival was not  
6 statistically significant on Mantel-Cox testing. (p=0.27).

7

8 **Figure 2. Survival by Resection.** Median survival following en bloc resection was undefined.  
9 Median survival following intralesional resection was 17.8 months. Survival following en bloc  
10 resection was significantly different than survival after intralesional resection on Gehan-  
11 Breslow-Wilcoxon test (p = 0.049). The survival difference was not statistically significant on  
12 Mantel-Cox testing (p=0.07).
